LETTER TO THE EDITOR:

LIPID CONTENT OF HUMAN FALLOPIAN TUBE†

Sir,

Very little information is available on lipid constituents in human Fallopian tube. Histochemical investigations (1) reveal that lipids are more conspicuous at the time of ovulation or shortly thereafter, but are depleted at menopause. The present report describes the total lipid and the phospholipid content of human Fallopian tube under different physiological conditions viz., (i) normally menstruating, (ii) Amenorrheic (lactational), and (iii) 24 hour post-partum. The tissues of the cyclic women were grouped separately for proliferative (8-12 days) and secretory (16-20 days) phases of the menstrual cycle.

Pieces of Fallopian tubes were collected from women in reproductive age group (25-40 years) who underwent tubectomy in a local family planning clinic. Total lipids and phospholipids were estimated as described in a previous communication (3).

The results presented in Table I show the total lipid and phospholipid levels of human Fallopian tubes. No significant differences were found between the proliferative and secretory phases. This was also true for the values obtained in the Fallopian tube of post-partum and amenorrheic (lactational) cases. It may be pointed out that the

total lipid and phospholipid values in the human Fallopian tube are considerably higher as compared to the Fallopian tube of rhesus monkey (2.3).

ACKNOWLEDGEMENTS

The author is grateful to Dr. Nitya Nand, Director, and Dr. P. R. Dasgupta and Dr. B. S. Setty for their interest in this investigation. The technical assistance of Mrs. S. R. Srivastava is acknowledged.

This investigation was supported by a grant from the Ministry of Health and Family Welfare, Government of India.
