Summary: The adult Wistar strain albino rats were vasectomised by conventional method and maintained for six months. The vasectomized rat testis had elevated water content with depleted dry matter. Glycogen content was increased with indication of mobilization of hexoses into HMP pathway. The vasectomized rat testis showed preferential utilisation of triglycerides. In view of increased 3 $\beta$–HSD and 17 $\beta$–HSD activities, accelerated androgenesis was envisaged in vasectomized rat testis.

Key words: vasectomy, testis, phospholipids, leydig cells, androgenesis, cholesterol

INTRODUCTION

Vasectomy has been employed as an important male contraceptive device. But a number of side effects have been reported both in man and animals (6, 23). There are several conflicting reports regarding the effect of vasectomy on the male reproductive system (16, 20, 23) while some investigators reported impaired androgenesis (20, 23), the others suggested improved androgenesis and leydig cell proliferation (24, 11, 20). Hence, an attempt has been made in the present study to evaluate the possible side effects of vasectomy on general metabolism of testis.

MATERIAL AND METHODS

Healthy Wistar strain adult albino rats of 145±2 days of age and weighing 250±5 gms were used for the present study. Rats were divided into two groups and one
group of rats were subjected to bilateral vasectomy by conventional method through abdominal approach as suggested by previous investigators (21) and the rats were maintained as per standard procedures. The other group of animals were sham operated and taken as controls. After six months of vasectomy both control and experimental animals were autopsied by cervical dislocation and the testes were immediately excised. The wet weight of tissue was determined and used for further analysis. The following estimations carried out using standard procedures. Tissue somatic indices, water content and dry matter were estimated gravimetrically. The glycogen (12), glucose (15), sorbitol dehydrogenase (18), glucose–6–phosphate dehydrogenase (2), total lipids (8), triglycerides, free fatty acids and cholesterol (19), glycerol (5), phospholipids (4), lipase activity (10), 3 β-Hydroxy Steroid Dehydrogenase (3 β-HSD) (3), and 17 β-Hydroxy Steroid Dehydrogenase (17 β-HSD) (3) were estimated.

RESULTS

TSI of the testis after vasectomy remained unaffected (Table I). While the water content was elevated, the dry matter was significantly decreased. The glycogen content was drastically elevated with decrease in free glucose level. The activity levels of sorbitol dehydrogenase and G-6PDH were considerably increased. The total lipid content was increased in vasectomized rat testis over the control level (Table II). The

Level of triglycerides was decreased with elevated lipase activity while the glycerol content was elevated, free fatty acid content was decreased. The levels of phospholipids and cholesterol of vasectomised animal testis were increased. The activity levels of 3 β-HSD and 17 β-HSD were significantly increased in the testis after vasectomy.

**DISCUSSION**

The testis of vasectomized rats after a prolonged period showed no significant change in tissue somatic index from control, which was suggestive of maintenance of fairly constant size of the testis after vasectomy. However, there was considerable increase in the water content which might be due to active uptake of water from the blood for hydrolytic activities, since the vasectomized testes recorded degeneration of the tissue (14, 23, 25). Since the dry matter was highly reduced, increased hydrolytic activities...
resulting into overall degradation of organic components can be expected, which might reflect on the increased uptake of water. Accumulation of water by the tissues under atrophic conditions have been reported (11, 14, 22, 24) and hence water accumulation by the vasectomized testis was suggestive of active atrophic conditions in this tissue. Since carbohydrate and lipid fractions of the testis play vital role in the testicular activity, an attempt has been made to analyse some aspects of carbohydrate and lipid metabolism of tissue after vasectomy. The tissue glycogen content was highly elevated indicating the possibilities of increased glycogenesis and/or decreased glycogenolysis. Such an elevation in the glycogen content of vasectomized animal testis has been reported by previous workers (17). The values obtained in the present study were in perfect range of previous investigators. Lactic acid content of the testis of vasectomized rats was reported to be decreased (17), which was suggestive of decreased tissue glycolysis. However, sorbitol dehydrogenase activity was increased in the present study, which indicates active mobilisation of sorbitol into fructose and thereby increased fructolysis. The free glucose content was also considerably depleted. Under such conditions of inhibited glycolysis, mobilisation of hexoses into alternative pathways can be expected. The elevated activity of G-6-PDH was suggestive of mobilisation of glucose into hexose monophosphate pathway. Hence after vasectomy, there seems to be a shift in testicular carbohydrate metabolism from hexose diphosphate pathway to hexose monophosphate pathway. Since G-6-PDH activity is localised in leydig cells (9, 13), elevated enzyme activity suggests the activation of leydig cells after vasectomy. The previous observations indicating the proliferation of leydig cells of vasectomized animal testis (11, 20) were in support of such possibility. Such conditions result under active lipogenesis. Hence the testicular lipid fractions have been analysed for drawing correlations with changes in carbohydrate metabolism with testicular lipid profiles. The total lipid content was considerably elevated suggesting the possibility of increased lipogenesis. However, the triglyceride content was drastically decreased with an increase in lipase activity. This observation suggests the active mobilisation of neutral fat, into the testicular metabolism. Consequent on such an increase in the lipolysis, the glycerol content was elevated. But the free fatty acid content was depleted indicating the mobilisation of these components into oxidative metabolism. Hence after vasectomy the testicular metabolism seems to be oriented towards lipid oxidations resulting into decreased triglyceride content and elevated glycogen content. Such lipid utilisation property was associated with the testis under inhibited spermatogenesis (7). The phospholipid content was considerably elevated suggesting that the vasectomised animal testis was actively involved in the synthesis of phospholipid fractions. Since phospholipids were known to be associated with active transport mechanisms and biosynthetic activities (1) their increase in vasectomized rat testis was suggestive of the possibility of increased synthetic activities of the tissue with
promoted active transport processes. The cholesterol content of the tissue was drastically elevated suggesting stepped up steroidogenesis of the testis after vasectomy. This observation was in concurrence with the earlier reports (17, 25). Hence increased denovo synthesis of cholesterol in the testis can be expected. In order to understand the formation of androgens, key enzymes of the pathway have been analysed. 3 β-HSD activity, which marks the formation of progestogens was markedly increased suggesting mobilization of cholesterol into the steroid hormone formation. Similarly, the activity level of 17 β-HSD which marks the formation of testosterone was considerably elevated which was suggestive of increased androgenesis of the tissue. Since proliferation of leydig cells was witnessed in vasectomized animal testis (11, 20) and leydig cells were concerned with androgenesis, increased activities of 3 β-HSD and 17 β-HSD were indicative of stepped up androgenesis in the testis after vasectomy.

In general vasectomized rat testis showed a shift in metabolic mobilisation of organic compounds from carbohydrates to lipids, which might be responsible for inhibited spermatogenesis, reported by earlier investigators.

ACKNOWLEDGEMENTS
